

Observable import adds map, catch function to core Observable available in Angular.

UserService class then declares dependency on Angular Http service in its constructor which is provided to UserService by Angular at runtime.

Basic pattern involved in working Http service is call one of its method then chain together multiple functions to its returning Observable for handling server response.

In above example we call `http.get` method with the user data api url, which returns the Response object if successful. We use map function to convert output data type from the Response to array of `User[]`, Here a ES6 lambda is used to retrieve data from Response object using `.json()` and also type cast it to `User[]` array so that typescript can do type detection on resulting variable.

The last chained method `catch()` handles the error case, If any error occurs in Http call, the catch function passes the error object to `handleError` method, which in turn presents it to consumer of `getUser()` service as Observable with required error information for debugging. This ensures that consumer of `getUser()` always deals with Observable.

We could also write above get users functionality in form of Javascript Promises. Here's an example:

Code can be found here: <http://pastebin.com/ytB5ZMZy>

The Http service is the major communication tool with the server/backend
