

The delete request conveys the removal of data

Http Head request

Http Head request is identical to get request except server doesn't send any content in response body, only the http headers are sent back to client of http call. The http headers sent in http head call are supposed to be exactly similar to that of equivalent http get call. The http headers convey the meta information about the data given by http get response body. This is useful for testing whether web url is valid and accessible or detect whether they are currently modified.

In angular we make Http head call using the `head()` method available on the Http client.

Code can be found here: <http://pastebin.com/wH82892b>

Here we are using http head call to detect whether any user exists with given id, it's strictly demo example and not to be used in production.

`http.head()` uses similar pattern to that of http get. We are passing the unique hyperlink used to identify the required user, i.e by forming url with base users api and the user id. We make http head call with this url and the same request options that we used for retrieving the users from server. If this operation is successful we return the Javascript Promise with true boolean value, else we return rejected Promise with value false.

JSONP requests in Angular

All internet browsers follows a same-origin policy. Under the policy, a web
