

JSONP essentially means JSON with padding, where JSON is JavaScript Object Notation

browser permits scripts contained in a first web page to access data in a second web page only if both web pages have the same origin. i.e. same combination of combination of URI scheme, hostname, and port number. Basically any executable script in web page is not allowed to make cross domain http requests.

JSONP (as in “JSON with Padding”) is a method commonly used to bypass the cross-domain policies in web browsers. JSONP requests are not same as above http get, post, put, delete

requests. JSONP requests are normally read only and are not dispatched using the `XMLHttpRequest` (and the associated browser methods). It was developed because handling a browser’s same origin policy can be difficult, so using JSONP abstracts the difficulties and makes it easier to communicate with cross domain http request.

To understand a JSONP requests, consider a simple URL that returns the JSON data, <http://example.com/api/users/1>

The http get response body for above url,

```
• {
•   "id": 1,
•   "name": "jack"
• }
```

Here, an HTML `<script>` element specifies for its `src` attribute a URL that returns JSON:

```
• <script type="application/javascript" src="http://example.
com/api/users/1">
•
• </script>
```

The browser will download the script file, evaluate its contents, interpret the raw JSON data as a block and throw a syntax error. Even if the data
