

ROUTING

An Angular application's very own navigator system

Any website on Internet seldom contains only a single page. Most of them are simply collections of separate web pages which are accessible using their own unique URL. Such websites have some kind of navigation on the main page, that is the main page contains the links to the other pages identified by relevant text and visual feedback (blue underlined text). We called those links hyperlinks. A user moves around the website by clicking on the hyperlinks provided on the page. In this way, a web application differs from that of desktop application as the web browser has to load the entire web page on the click of a hyperlink and discard the previously displayed content.
