

Importing the router

The Angular router is an optional service and is required to be imported explicitly. the router resides in `@angular/router` library. we can import required routing dependency using the following.

- `import { RouterModule, Routes } from '@angular/router';`

Basic example

We will use a basic example to demonstrate the angular routing feature. Our example is made up of just three screens, with links for each one at the top.

Configuration

The angular router needs to be configured with the application routes. The route object has a path segment, that is the URL and a component to be displayed, or redirect to another URL. Whenever browser changes its current URL, the routers goes through all the routes checking for path match, and depending upon the route takes appropriate action.

The Route Specification

An array of route configurations is known as Routes. Each one has the following properties:

- path is a string that utilises the route matcher DSL.
- pathMatch is a string that specifies the matching strategy.
