

adding leading slash to the path segment. The router parses and builds the URL for us, allowing us to use relative and absolute paths when navigating between application views.

We bootstrap the application using AppComponent declared as follows,

```

• import { Component } from '@angular/core';
•
• @Component({
•   selector: 'my-app',
•   template: `<a>Home</a> <a>Screen1</a> <a>Screen2</a>
<hr>
•   <router-outlet></router-outlet>`
• })
• export class AppComponent {}

```

Notice the `<router-outlet></router-outlet>` tag at the end of template. The router displays the contents of activated component after the `<router-outlet></router-outlet>` tag.

Remaining components just displays its own name, these are declared as follows,

HomeComponent

```

• import { Component } from '@angular/core';
•
• @Component({
•   template: `<p>This is home.<p>`
• })
• export class HomeComponent {}

```

Screen1Component

```

• import { Component } from '@angular/core';
•
• @Component({
•   template: `<p>This is screen1.<p>`
• })
• export class Screen1Component {}

```
