

Screen2Component

```

• import { Component } from '@angular/core';
•
• @Component({
•   template: `<p>This is screen2.<p>`
• })
• export class Screen2Component {}

```

PageNotFoundComponent

```

• import { Component } from '@angular/core';
•
• @Component({
•   template: `<p>Page not found.<p>`
• })
• export class PageNotFoundComponent {}

```

We have now working code that just displays the “This is home” message on screen. We still have not added the navigation links to AppComponent.

Now let’s add code to move between the screen1 and screen2 components.

```

• import { Component } from '@angular/core';
•
• @Component({
•   selector: 'my-app',
•   template: `<a routerLink="home"
routerLinkActive="active">Home</a>
•   <a routerLink="screen1" routerLinkActive="active">Screen1</a>
•   <a routerLink="screen2" routerLinkActive="active">Screen2</a> <hr>
•   <router-outlet></router-outlet>`,
•   styles: [`a.active { font-weight: bold; }`]
• })
• export class AppComponent {}

```

For each anchor tag in the template, we have added routerLink and routerLinkActive directives.

The routerLink directive has specified one time binding to specified URL. We could also bind dynamic value using template expressions. The routerLinkActive directive just adds the CSS class given by its value to the current tag when that link is activated.
