

that the framework itself is at fault or is not as amazing as everyone claims. Our understanding of angular and its best practices are therefore very important if we are to design serious applications on it.

Naming Conventions

Naming standards help developers to understand each other's code better and keep everything tidy. Naming standards exist for filenames, class names as well as selectors. Of course a comprehensive discussion on naming conventions would require another fastrack by itself (albeit a tad boring one!), but now let us cite you just a few examples. We strongly recommend that you visit the official angular style guide's site to ensure that your application follows the highest of standards in angular naming conventions.

Following a naming convention will ensure that another developer does not have to pull out his hair while looking at your code

Keep it short:

- File and folder names should use dash-case and have a suffix which refers to their functionality, like: `*.component.ts`, `*.service.ts` `*.interface.ts`
- Selectors should also use dash-case and have a prefix, which functions as a namespace.
- Classes (components, services, directives, etc.) and interfaces should use camelCase and have a suffix which refers to the type of the class, like: `*Component`, `*Service`, etc.

Directory and File Structure

It is a tough job to keep directory and file structure standardized due to the sheer number of these items in an application. The demands always change project by project. Your directory structure might differ from
