

the official style guide but still be easier for you to navigate/maintain. In the official style guide you use shared folder (for common components, styles, etc.).

In another version, common components to component folder, directives to directive folder etc.

Only global services go to services folder.

Keep tests close to to source code.

CLI/Boilerplate

Beginners on angular 2 should use angular-cli (npm i angular-cli -g). You can generate a good example with `ng init project-name`. This command will initialize a new Angular 2 application that should already be working and follow all the best practices from the official Angular 2 style guide.

Additionally, it installs the required npm dependencies. It also creates unit testing and e2e testing scripts. In short, it does everything required to start a new Angular 2 application.

Such a boilerplate standard practices applied application would be great to learn as a standard that all angular applications need to adhere to.

Documentation

Documentation is crucial when building and maintaining code in a collaborative environment.

It allows faster and easier understanding of code, reduces ramp up time for new development stories and allows better transparency all across the application.

There are many useful tools on the market that automate the process of generating documentation from your angular 2 code, one such tool is typedoc.
