

Typedoc is in many ways similar to JavaDoc, allowing you to create HTML documentation based on TypeScript classes. It compiles all the documentation (classes, namespaces, functions, etc.), puts them under the doc folder in the current directory where that command is ran. The only fall through here is templating, which is a tad bit difficult on it.

Testing

Testing angular or rather JavaScript in general has always been a low priority issue since the general perception was that server side services need to be much more battle tested than client side code, but with Node.js in the market and the extensive use of frameworks like angular to create complex client side applications and SPAs, testing has become far more critical for these frameworks too.

Although many libraries have come up that allow you to test your angular application, most (like

Karma) have an over complicated architecture or are just out of beta (Mocha). We suggest using only jasmine. It contains a lot of good examples of testing boilerplates and patterns.

Do remember to always compile a .ts file to JavaScript before running tests on it.

Documentation has saved many a developer when a project failed
