

ered best to not change them while editing. Obviously there are exceptions, but for starters, it's best to make this choice beforehand and stick with it.

Resolution

Resolution is not just a measure of the quality of the video but also the file size. If you don't own a decently powerful system or a strong internet connection it would be hard to work with higher resolutions like 4K. So making an optimum choice which suits your infrastructure is required. Although it is also important to keep in mind the current quality expectations of the industry. In the time where the world is transitioning to 4K, making a 480p video is not a great choice.

Another aspect of resolution is the aspect ratio. Aspect ratio determines wideness of your video. The ratio is between the width of the image and its height. The most common aspect ratio is 16:9. The 1080p resolution is part of the same family – 1920 pixels wide and 1080 pixels high. The 'p' stands for something which has become irrelevant in the modern age. But just for the sake of knowledge; 'p' stands for progressive. It is one of the two ways a screen displays images. The other one, interlaced is when the rows of pixels are displayed in two groups, to reduce the load on the screen or projector, that's the 'i' in 1080i. Progressive displays all the pixels in one go. As the modern display systems are quite powerful, interlacing has almost become obsolete.

Other than 16:9, 21:9 and 4:3 are common aspect ratios, though 4:3 is not as common on YouTube due to the type of content prevalent on the website. The choice of aspect ratio is also widely based on the genre of your video. A narrower aspect ratio is suited for a dramatic and domestic video. On the other hand, a wider aspect ratio is used for more action packed or large-scale shots. The larger frame estate gives enough breathing space (remember this term) for the dynamic nature of shots in such films. Because there aren't many slow-baking dramatic videos on YouTube or epic scale of a giant budget, 16:9 is seen as the ideal aspect ratio. But obviously, there's nothing wrong in experimenting. Keep in mind, YouTube's player is natively 16:9, everything else would be displayed with black bars.

Frame rate

Next core specification of a video is the frame rate. It is the speed at which each frame of a video changes. Universally this rate is accepted to be frames per second or fps for short. The choice of frame rate is again a bargain between content and file size of the video. Higher frame rate means more
