

The console doesn't use DVD or Blu-ray discs. Instead it uses another high density optical disc format that it co-developed with Panasonic which is capable of holding upto 25 GB per layer.

The Wii U is compatible with all the Wii accessories and games. Nintendo also came out with a 'Virtual Console' service that let users play NES and Super NES games on their Wii U.

The Wii U met with mixed critical response when launched. Though the console was a significant leap over its predecessor, it couldn't match its competition's game library or graphical prowess. Many big publishers including EA and Ubisoft announced that they will not be working on as many games for Nintendo's console citing the decreasing sales of Wii U as the primary reason behind the decision.

Wii U's production was finally discontinued worldwide on 31st January with Nintendo getting ready to release its next generation console dubbed the 'Switch'.

Sony PlayStation 4

Sony's PlayStation 4 was launched in North America in November of 2013 and across the rest of the world by early 2014. It is the most powerful home console to date produced by Sony running on an Accelerated Processing

Unit developed by AMD which they billed as the 'most powerful' APU developed by them till date.

The console had a number of nice features including letting you live stream your gameplay online, connecting your PlayStation Vita or selected Sony Xperia devices to the console and much more.

Sony launched an updated version of the PS4 called the PS4 Pro with upgraded hardware.

The PlayStation 4 features a new version of the DualShock controller that comes with a touchpad on the front of the console and supports motion sensing using the inbuilt gyrometer and accelerometer.

Learning from its history, Sony knew that it needed to make this generation of its console more developer friendly. Hence, the hardware found on the console is very similar to today's personal computers.
