

lead to construction of digital logic circuits within living cells representing logic-levels by concentrations of DNA-binding proteins.

Beating the Clock

Sun labs has been working on FLEETzero – a prototype chip with raw speed roughly twice that of today's chips. That speeds up everything by two - including our very lives. The new approach embodies the asynchronous principle that allows the logic itself to manage the time and resources required to move data. This simplifies design by removing the need for circuitry to manipulate a system clock

Imagine the possibilities with computers made of human DNA

In conclusion, it can be said that SoC and ASIC design have suffered huge evolutionary changes in a very short time span. The next important step would be to standardize the medium so that the evolution occurs at a faster pace with a large community working together on solving the same problems. The design will get better and the CPUs will get faster, thus paving the way for faster, smoother and more sophisticated devices. **d**
