

The stereotypical hipster's combo – coffee and code

from, as well as what goes into it. Here are some of the nitty-gritty details of the company's borderline obsessive hardware innovations.

Processors - need for speed

The Mac range mainly uses Intel's x86 line of processors – typically the most advanced generation there is, currently the seventh. As always, there are stripped down versions of the Mac, with basic features, but that's not what you're here to read. The Mac processors procured from Intel have a nifty 'Turbo Boost' feature, wherein the operating system responds to heavy system load by activating a higher processing frequency state. Of course, this comes at the expense of power consumption, heat generation, and ultimately, the life of your machine, but it can be a great help in a pinch.

The iMac is available with a beastly 3.0 or 3.4 GHz quad-core Intel i5 processor, with Turbo Boost upto 3.5 and 3.8 GHz respectively. The mini is arguably slightly disappointing, with the same make, but only 2.6 or 2.8 extendable to 3.1 and 3.3 via Turbo Boost. The Mac Pro is the behemoth of processing power, mainly intended for high-performance scientific computing, graphics design, or photo editing. It offers the massive Intel Xeon E5 line, with 6-core 3.5 GHz or 8-core 3.0 GHz, both Turbo Boosting to 3.9, with on-board L3 cache memory to add to it all.
