

Apple's line of personal computers - Macintosh - is powered by Apple's in-house operating system since 1984. Dubbed as the "classic" Mac OS back then, the operating system has gone through a series of changes to its features as well as the name. Starting from 2001, Apple changed Mac OS to Mac OS X whose versions were named after big cats. The "X" in the name stands for "ten" and also showcases its UNIX lineage.

From 2013, the naming trend changed to landmarks in California instead of big cats. Adopting the nomenclature that they use for their other operating systems (iOS, watchOS, and tvOS), the OS X versions starting from 2016 are called "macOS". The latest publicly available version of macOS is macOS 10.12 dubbed as Sierra. The next version macOS 10.13 slated to be called High Sierra is also announced but will be publicly available in Fall 2017.

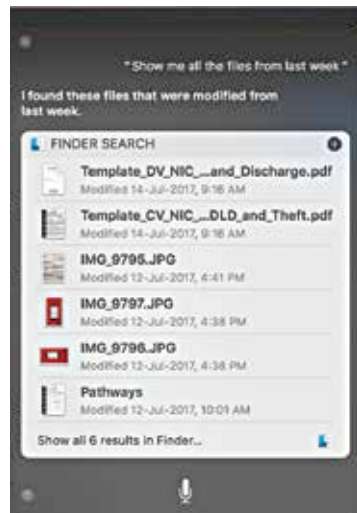

Features

macOS packs a plethora of features to enhance your Mac experience. Some of these features are exclusive to Mac while others share similarities with features in the larger Apple ecosystem. Apple currently seems to be in the process of integrating a lot of features from its other operating systems. One such addition was the introduction of "Siri" to Mac.

Siri

Apple introduced Siri in the year 2011 in its iOS release. Since then, the personal voice assistant has undergone massive improvement and has been a major part of Apple's ecosystem now. While iOS, tvOS, and watchOS showcased Siri, it hadn't made its way to macOS. Apple introduced this personal voice assistant to macOS last year. Siri on Mac is not as simple as the phone counterpart.

It is capable of executing tasks involving more complexity such as finding a file and finding documents by tags. For example, "Find me all the files that I opened last week". Siri can

Siri returns all the files that you modified last week
