

Over the past few years, Apple Watch has grown from something which was a glorified toy into a fully fledged smartwatch capable of not only letting read messages, set reminders and alarms, but also act as your dedicated health and fitness tracker.

All this had been possible because of regular updates of watchOS pushed by Apple. The current series of Apple Watch is powered by watchOS v3 with the v4 recently announced at the WWDC 2017 held in June, and is slated for a release in September, later this year.

So let's take a look under the hood of the Apple Watch and get acquainted with the software that makes it one of the best smartwatches right now.

The watchOS had an intuitive UI which is users can interact with using what Apple calls “the digital crown” – that's just the dial on the side. The home screen features circular app icons which you can cycle through using either the crown or the touch screen. The first two version of the OS contained something called ‘Glances’ which could be accessed by swiping up from the bottom of the screen, letting you view summarized information from various native or third party applications at a glance. Neat, right? This was replaced by a control center similar to what exists on the iOS platform.

Lets checkout the various features and highlights of each version of the OS, and see what's yet to come.

Apple Watch currently holds the largest share in the smartwatch market
