

Mac required only WiFi. This was fixed with OS X Yosemite's release in 2014, allowing the phone to establish simultaneous Bluetooth and WiFi connections with the Mac. Most Macs that were released in the last decade can use the legacy WiFi only AirDrop to transfer files but for iPhone - Mac transfers, you'll need to have a device from 2012 or later.

You can access AirDrop by swiping up into your control center while on MacOS, AirDrop is available in the Finder's sidebar. Most 'Share' dialog boxes will also have AirDrop listed as an option. Do note that enabling AirDrop will turn on WiFi and Bluetooth on your iPhone (because both of those are leveraged) and WiFi on your Mac. Once you initiate the transfer, the receiver must choose to receive the files and you're done. (This is done automatically if both the devices are signed into the same iCloud account)

Down with the wire tyranny!

Allrighty then, the future is here, let's destroy allllll the cables and become wireless overlords! Well.... Not quite. For starters, it requires you to invest quite heavily into the Apple ecosystem and who are we kidding, even owning more than one Apple device is a huge obstacle in India. Premium pricing

is well and good until you get the short end of the stick. And even if you are invested in the ecosystem, transferring files to friends and family is going to be hard if they don't have an Apple device. Furthermore, a wired connection will always beat a wireless one in terms of both speed and quality of the data transferred. While it is improving (by a whole lot) and is definitely a viable alternative, a lot of people would still prefer a wired connection. Maybe someday, Wireless connections will finally break the speed boundary imposed by a physical medium and be much faster and

This Everyone option is for those who like to live on the edge
