

background to the objects, frame by frame. Animation and rendering is done by an SKView object. Content is rendered in a window where you're free to combine and move views around hierarchically. Once you're done you've created a scene, represented by SKScene objects. These scenes are what you organise to form the frames for your game.

What happens in scenes is determined by Nodes, represented by SKNode. Nodes are present in a tree or branch like structure which determine how content is rendered and actions take place. Keep in mind, the Node class itself doesn't draw anything, it just determines when its subclasses should take action. Following this you have Texture objects and Nodes that execute animations and body objects to simulate physics and movable joints etc.

This is just a basic explanation, it's far more complicated than this, but documentation on how to use these frameworks is freely available online.

Now let's move on to Apple's desktops, the Mac.

Gaming on a Mac

If you're hellbent on gaming on a Mac, you're going to have to keep a few things in mind. Here, we'll go through those things.

Compatibility

Casual games will run just fine on a Mac. Even older games shouldn't have too many problems, at least when it comes to hardware requirements. The biggest thorn in that path would be compatibility, since many of the older games are not compatible with Apple's macOS. However, it is possible to circumvent this issue by installing Windows on your Mac via Boot Camp. But that's kind of cheating in a way. Regardless, a lot of games releasing these days come with support for Mac so you don't have to worry all that much. Even Steam and a lot of the major players (i.e, EA Origin, Uplay etc) are Mac compatible now with several games that release Mac-ready. Of the almost 15,000 titles on Steam right now, 5095 games are compatible with the mac. That's 33 percent, or almost a third of all games on Steam.

GPU and Display

Gaming can be quite taxing on a system. There's a reason you have those bulky graphics cards installed into your systems in order to run games smoothly. Now if you look at a Mac, they're rather slim and tend not to take up too much space. Apple prefers to keep it that way. So you won't be seeing any bulky cards that might compromise that slimness in a Mac,
