

iPhone vs iPhone 3G

with some plastic backing, a 3.5 inch screen with a resolution of 320x480, 128 MB of RAM and a whopping 1400 mAh battery. It ran on iPhone OS 1.0, Apple's first attempt at the software that would slowly evolve into iOS.

3G and 3GS

On June 9, 2008, Apple released the iPhone 3G. (it

might come as a shock to some millennials that there was no iPhone 2) It was called the 3G because while it was pretty much identical to the original iPhone, it included several hardware upgrades like a GPS sensor and most importantly, a 3G Radio. It also had a hard plastic back instead of aluminium and featured iPhone OS 2.0 – whose SDK Apple released to let developers develop 3rd party applications for it.

The 3GS which was released almost exactly a year later, featured many upgrades from the 3G. The S stood for speed and it showed. The amount of RAM was doubled to 256 MB, the iPhone OS (the name changed to iOS with this generation) started maturing enough to get optimised, the processor was given a hefty upgrade and especially the camera was completely overhauled to now include a 3 megapixel camera unit.

4 and 4S

This marked the first major hardware change to the iPhone family so far. The iPhone 4 featured a stainless frame sandwiched between two panes of aluminosilicate glass. The steel wasn't just for show either – it functioned as the phone's antenna. The iPhone 4 also featured Apple's now rapidly becoming famous Retina display – a display with a high enough resolution that you can't tell individual pixels apart with the naked eye. It had a 960x640 resolution in the same 3.5 inch display. It also had the A4 SoC, Apple's homegrown processor that resulted in a huge speed bump from the 3GS. It also had a front facing camera, the first ever iPhone to do so. The iPhone 4 had the longest product lifetime of any iPhone.

Apple now set the tradition of releasing a design and improving it the next year, a sort of tick-tock product release cycle and released the
