

The lifeline of a majority of Apple's portable devices, iOS is liked by many and hated with equal fervour by the others for many reasons. Every year has brought to us a new version of iOS with iOS 11 being the latest which will be released later this year. The key aspect that makes iOS stand apart from the other operating systems that Apple has in its portfolio is that iOS is built for Touch first while Mac OS is built to be interacted with using some Human Interface Device (HID) or the other.

Over the years, iOS has come a long way towards making the user experience less cumbersome and more seamless with fewer proprietary walls to climb over but it still has some way to go before we'd call it the best mobile device OS on the planet. So let's start off by looking back at iOS' journey through the years.

The birth of iOS

Apple had the iPod under its portable devices portfolio and it was very popular at that time for having features that other media players could only dream of. However, the same UI and experience would hardly suffice for a phone which was what Steve Jobs was aiming for. The option was

either create a miniature Mac-like device powered by a lean version of OS X or considerably upgrade the minimalist OS that the iPod used. Apple went with a balanced approach, with iOS being significantly feature rich compared to the

older HDD based iPods but far from being comparable to the OS X. However, to make this happen, Steve Jobs had the Mac and iPod R&D teams compete with each other to see which of these approaches would result in a better product. The Mac team led by Scott Forstall ended up with the upper hand and thus, was born the iPhone OS in 2005 which would later be renamed iOS in 2010.

While the iPhone OS had been in existence since 2005, it would only be in 2007 when the general public would get to experience the new OS at the launch of the first iPhone in 2007. And like all operating systems that were ever created, even the iPhone OS was incredibly buggy. So much that
