

Force Touch is currently being used in Apple's 12 inch MacBooks, newer MacBook Pros and the Magic Trackpad 2.

Apple re-engineered this technology and took it to another level when they introduced 3D Touch with the iPhone 6S and 6S Plus back in 2015. The new touch screen works using capacitive sensors integrated directly into the display making them more sensitive than Force Touch. When a press is registered, the capacitive sensors measure the distance between the outer glass and the backlight panel, which then combined with the touch sensors is able to calculate an accurate feedback.

3D Touch is currently found on Apple's flagship iPhones like the iPhone 6S, 6S Plus, 7 and 7 Plus. You can of course expect more iPhones and iOS devices to adopt this feature in the near future.

Taking advantage of 3D Touch

Having a pressure sensitive display can add a lot of new functionality to touchscreen devices. App developers can take advantage of this technology to provide deeper controls and features. Here are some of the best implementations of 3D Touch right now:

- **Quick actions from home screen**

Applying a little pressure on any app icons that support 3D Touch, displays a quick access menu that lets you perform specific actions right from the homescreen. For example, pressing down the camera icon displays a quick option that lets you take a selfie, record a video, record slo-mo or take a photo.

- **Live Photos**

When taking any photo, Apple's Live Photos feature by default records a 1.5 seconds video of what happens before and after taking any picture from your iOS device. With the help of 3D Touch, you can make your photos come to life (with movement and sound) by simply pressing down on the photo.

- **Peek and Pop**

Peek and Pop allows you to preview any messages, links, emails, etc, on any apps that support it without having to open the application. On any app
