

its implementation isn't perfect and there are many usecases where Apple needs to put in more thought. Let's take a look at some of those:

- **Unique stand-out features**

Most of the functionality that 3D Touch currently offers can still be argued to be more gimmicky than useful. Gestures like the peek and pop or quick actions aren't anything extraordinary. Android phones can achieve the same result with a simple long press. Take apps like Instagram for instance, where you can use the same 'peek-in' feature on Android by simply pressing any photo a few milliseconds longer instead of hard pressing. Right now, Apple needs to work on newer software features that can actually take advantage of the unique hardware.

- **More apps support**

It's been two whole years since Apple first launched the iPhone 6S with 3D Touch, however, not many apps and games on the App Store support the feature. Even if they do, apps will need to spend some time "educating" users as 3D Touch actions don't come intuitively to users. All we can hope here, is for Apple to start pushing 3D Touch on more devices so app developers for iOS and OS X can work on bringing new and smarter features that can take advantage of the technology.

The future of touch technology

Ten years ago, when Apple introduced "multi-touch" on their first iPhone, it revolutionized the entire tech world. It completely changed the way we interact with our phones and other touchscreen devices using pinch, taps

Various layers that make it work
