

and swipes. Although, the origins of multi-touch as a technology was first born in the labs of MIT, CERN and few other universities during the early 1970s, it was Apple that later perfected and popularised this technology. And since then, touch technology is seeing improvements with features like more multi-touch points support, quicker responses and sensitivity, etc, but the upgrade has always remained gradual.

Then came Force Touch and 3D Touch. Although it's still in infancy, with better software and hardware development, this technology could be a breakthrough. Imagine in the future having a pressure sensing display that can identify between different pressure levels of touch, register the feel and actually mimic it artificially with the use of electrodes and electrical currents only. Say your touch screen touches you back or transmits a touch from another person virtually. We've already come a very long way and honestly, this future does not seem to be too far off.

And until the day arrives when we start carrying tiny wearables that project holographic interactive displays and wear crazy virtual headsets, 3D touch seems to be taking the right direction towards improving the immersion levels offered by the tech around us. **d**
