

## **“I’m feeling Lucky”**

Introduced in the year 2012, and meant to eliminate one step in your search activity, the “I’m Feeling Lucky” option of the Google search takes you to the first search result directly instead of bringing you to a page with multiple search results.

Placed literally right below the Google search bar, this feature is the road you take when you know exactly where you have to go.

Now practically this makes the most sense when you have to log in to certain websites. For instance, if you were to Google ‘Stumbleupon.com’, instead of coming to a page with multiple search results, the “I’m Feeling Lucky” option takes you directly to the login page of the website. Same goes for social media websites like Facebook, Twitter, Youtube, etc. It’s not as popular as Google would like though.

## **Conversational Search – OK Google**

In 2013, Google announced its conversational search option for desktop, which was earlier available on Android and iOS.

The present version of Google Voice Search talks back to you, unlike earlier when it was all one way, and all you did was speak your search query into a microphone. Google voice search has transitioned from the command-phase to a literal conversational approach where the voice assistant also reads out your search results.

Although the voice search on your mobile phone will recognize your voice thrice while setting it up, it is highly likely that the search assistant can become hard of hearing, and provide you completely different results. This isn’t your fault, because no matter how clearly you try and enunciate your query, Google will just get it wrong. It hates all accents but the American one.

On the desktop, you would need to click on the microphone button in the corner of the Search bar every time you want to search for something using your voice – which makes it not hands-free, and totally pointless. Even Google can be idiotic at times.

What’s good about conversational search is that it remembers what you searched for before, and thus you can have a “conversation”. For example, if you ask Google, “Will it rain in Delhi tomorrow?”, it will respond with the weather forecast. Now if you ask, “What about next week?”, it understands that you mean “Will it rain in Delhi next week” and responds accordingly. Of course this doesn’t always work, and if you make the next sentence too long it will respond with something totally random, but it’s getting there.
