

are placed nicely across the bottom, or out of the way, as shown in the image alongside.

There are common ad formats which are used in apps as well, just as on websites. These include text, image and video ads. Games, especially, are notorious for using video ads. Some are skippable, while some aren't, depending on why the video is running. For example, some games give you lifelines, or allow you to continue your game from the point you died (in-game death), by watching a 30 second video. You get entertainment and high scores, the developers get a little money, and it's win-win. Developers get even more money when the ad is for another app, and clicking on the ad takes you to the app

store page where you're prompted to install it. If you like the app you're using, support it by clicking on such ads, even if you don't install the app!

Data is used across apps as well. Say you're using two different apps which use the Google ad network. In the first app, you look for good deals for shoes, and then close the app. Now you start playing a game, and you might notice attractive offers on shoes showing up in the game's advertising. This is Google at work, trying to sell you stuff.

As an app developer, whenever a user clicks on an ad, you are paid the relevant amount. You can also become the advertiser using AdMob, and doing so adds in the functionality to push ads for your app to other apps signed into the service. If you're looking to grow the popularity of your app, AdMob is something you need to take serious note of. **d**
