

would change Google's presence forever. Android would go on to become the biggest OS in the world, making competition look ancient. The philosophy was simple, and the implementation was done right. Google probably won't have realized how important this platform would become for their future. Google was already pretty big with the search engine and YouTube. But this made Google a gargantuan entity. We shall take a good look at all things that make Android the most important OS and what plans Google has for it.

Android Inc.

Like almost all major technology breakthroughs of recent times, Android was conceived and created in Palo Alto by Rich Milner, Nick Sears, Andy Rubin and Chris White in October 2003. They called their company Android Inc. and wanted to

In 2014, Andy Rubin left Google to work on his Hardware incubator

create an operating system for digital cameras. They pitched Android as a digital camera OS at that time, but pretty soon they realised the bigger picture. Their idea of an open source operating system could potentially support any device with a touch display. So they decided to start pitching Android as a handset operating system as a rival to other touch based systems like Windows Mobile and Symbian. Android's kernel is designed around the Linux kernel. It was tailor-made to be perfectly compatible with handheld devices. Android Inc. was bought by Google in 2005 for a price no less than \$50 million, with all four of the founding members joining Google as well.

No one really knew about Android at the time. Also, at this juncture Google's intentions about entering the mobile market was completely unknown. Android finally developed into a mobile device platform, powered by the Linux kernel. The unique selling point was that it would provide an easily upgradable and flexible system with timely updates. The pitch was targeted at both handset manufacturers and carrier companies.
