

It is interesting to note how much of our time on our devices, especially desktops and laptops, is spent on a web browser. In fact, if you ask any member of Team Digit, they'll tell you that at any given point of time they have a multitude of tabs open on their browser for all kinds of tasks – word processing, email, instant messaging, social media, web-based design apps, CMS and even multimedia streaming websites. And that's just what we are limited to. There's a world of possibilities in your web browser and Google was never a company to miss an opportunity where there is one. That is where the entire Chrome project comes in.

The world in a browser

While the next chapter will go into much more detail about the Chrome OS itself, we need a little primer to understand what we are dealing with here, before we go into the devices in the ecosystem. So, ChromeOS, in the simplest terms, is an operating system whose central focus is a web browser. Almost everything you need to do can be done within that web browser, and for what can't, Google has built applications and other features to handle that. And with that focus, Google has developed an ecosystem of devices that cater to a range of needs. These needs can be broadly classified into two areas – education and business. While the Chromebooks pretty much single-handedly make up the education segment, their business counterparts comprise of the slightly beefier Chromeboxes, Chromebase as well as the portable Chrome Bits. Let's have a look at these in that order.
