

Your future car will run on electricity... and Android

automobile manufacturers to collaborate and build on. Having a common software platform helps in tackling security threats, and also build application support. As of now, the likes of Volvo and Audi have partnered with Google in this space.

While Google has enjoyed a head start in the autonomous car space, and even with its system-on-interface car system Android Auto, it is seemingly yet another contestant in the connected car race. Despite being one of the most successful with its prototype tests, Google is still tangibly far from introducing a driverless car running on its technology. All of this brings up one point, where Google, despite practically being the forefather of sorts for connected car technology, has not yet managed to deliver sound end products yet (apart from Android Auto, which also has many areas to improve on).

The next three years will be crucial in this space, and by 2020, we at least expect to see Waymo open an autonomous ride sharing service, and Google's Android interface in cars becoming increasingly commonplace.
