

Google Cloud makes large, bulky server farms like these obsolete.

- Once your Google cloud account is created and set up, go to the compute dashboard and create a VM instance using the wizard.
- Select the boot disk image to include your choice of OS (preferably Linux).
- In the firewall section allow Http traffic. This ensures that the VM is accessible over the internet.
- Once the instance has completed initializing you can view it in the dashboard with the status as running. The VM is now running and can be logged into via SSH.
- To log into the VM via SSH, click on the SSH button under the Connect tab. This should open up a pop-up that connects to the machine via SSH and opens up a terminal.

So we have successfully created a VM on Google Cloud and connected to it via SSH. There is another equally important service provided by Google that we will now look at. Google only charges for the amount of time the compute engine is executed, in per second fractions, i.e. if the VM only runs for 8 hrs per day the billing includes only those hours and not the entire day.

## Cloud Storage

Google cloud storage provides a low latency, highly redundant and reliable storage for a large variety of data, from live captures to archival data. It is
