

few who could afford it. At least until Google announced that it would be offering FREE internet plans at upto 100 mbps speeds and would keep gigabit internet at 'competitive rates'. And by competitive rates, if Google meant they'd provide gigabit internet with insanely huge FUPs at lesser than the average competitor's rate, they'd have been absolutely correct. With the cost out of the way, Google faced another problem with the audience. While the richer sections of Kansas City were extremely enthusiastic, the poorer sections showed no interest, even in the free plans. So Google sent out a team of 60 individuals to promote digital literacy and to hopefully conquer this digital class divide, which ended up as a success. Google purchased miles of 'dark fiber' – as in optic fiber already laid out but that wasn't being used from networks like liNKCity and used a rather ingenious way for the last mile, that is, the final leg of the connection from the ISP to your house. They installed aggregators of several different connections from houses, wired through the existing utility poles and these aggregators, named Google Fiber Huts, were simply integrated into the network. This avoided needless complications in digging up to lay cables to individual houses and allowed for faster adoption and lesser costs. Google Fiber grew from strength to strength and expanded across several counties in Kansas. Soon Google Fiber started expanding to other cities and as of now, is currently in 7 cities in the USA, like Austin, Texas and Salt Lake City, Utah, with plans of expanding to
