

Comparison between the top contenders in the PHP framework industry paints a very clear picture about Laravel's popularity

The Community - The community of Laravel users are known to be extremely inclusive, even of newbies just setting out down the path of web development. They are also extremely abreast of any new developments and help other members learn about these changes while they are relevant. This helps everyone using this framework to benefit from upgrades in a timely fashion.

Simple Is Good - Given the fact that Laravel follows all the conventions of traditional programming, it is easy for someone with the most basic knowledge of programming to jump ship to Laravel. Someone with the basic knowledge of PHP can have a 6-page web application up and running in a matter of hours. Who wants complicated when they can do simple?

Scalability - Laravel wins where most frameworks do not. It allows you to scale up extremely fast. You can go from using it for small web applications to rather large and complex ones almost overnight. This is what makes it an enviable asset in your developer's toolkit.

Security is Key - Cross Site Request Forgery or CSRF (also pronounced as C-Surf) is an attack on individuals to change information via a web application that they are currently authenticated in. This could mean the attacker gets the individual to change anything from their email id to transfer funds from their account. In cases where the affected individual has admin status on the app, the entire application can be opened up to attack. Laravel comes with built in CSRF protection. This makes it a valuable asset for web developers and the clients that they build apps for.

Testing Times - When new changes are introduced into a web application, there are high chances of it failing. The very stability of an app can be challenged every time changes are made. It is for this very reason that testing any changes becomes mandatory. Laravel does just that for its users. It has a Testing Unit that works around the clock on ensuring that newer modifications do not affect the stability of the application. **d**
