

in, middleware would detect that the user is unauthenticated and redirect them to the login page.

Apart from this, it can also do a host of other functions like giving titles and headers to all outputs, logging all incoming requests to a log book etc. A middleware can pass on the request to another middleware and so on and so forth till an action has taken place. Every middleware is a filter that can examine, pass on or reject the request.

The authentication and CSRF protection middleware are included in the Laravel framework and are located in the `app/Http/Middleware` directory.

You can also create your own middleware using the `make:middleware` Artisan command:

```
php artisan make:middleware CheckAge
```

Middleware decides which requests are given the go ahead and which are sent back with a rejection

This creates a `CheckAge` middleware and is located in the `app/Http/Middleware` directory. You can give a condition for this middleware that determines whether the user is to be given the go ahead to go further into the site or is to be redirected to the home page.

Artisan is the command-line interface (CLI) of Laravel which provides a number of helpful commands that can assist you while you build your application.

Let's say for example that you want to grant access to users that have supplied `age` above 200. The code would look like

```
<?php
namespace App\Http\Middleware;
use Closure;
class CheckAge
{
    /* Handle an incoming request.
     * @param  \Illuminate\Http\Request  $request
     * @param  \Closure  $next
```
