

```
use Illuminate\Support\Facades\View;
return View::first(['custom.admin', 'admin'], $data);
```

There are times when there is a data point that is common to all views like the user ID shown on the top of the page. No matter, where the user is, the ID is always displayed. You can share a data point using the share method.

URL Generation

Earlier, we saw that you might need to redirect a user to another page on your application or website. Or you might need to build links in your API. This is where Laravel provides you with several helpers that assist you URL generation.

You can generate an arbitrary URL for your application with the url helper. This will follow the same scheme (HTTP or [HTTPS](#)) and host from the current request:

```
$post = App\Post::find(1);
echo url("/posts/{$post->id}");
// http://example.com/posts/1
```

You can get information about an URL by

```
// Get the current URL without the query string...
echo url()->current();
// Get the current URL including the query string...
echo url()->full();
// Get the full URL for the previous request...
echo url()->previous();
```

You can also combine the `Route` function to define the URL. The benefit of this method is that it does not need an actual URL. So even if the target URL changes, you don't need to go back into your code to effect that change.

```
Route::get('/post/{post}', function () {
    //
})->name('post.show');
```

You can link a URL to this Route by

```
echo route('post.show', ['post' => 1]);

// http://example.com/post/1
```

If you have created a route linked to a URL that is publicly accessible, you should add in a security layer by appending a signature to the query
