

string. This signature verifies for you that the URL has not been modified since you created it. To create a signed URL to a named route, use the `signedRoute` method of the URL facade. You can also create a temporary signature with the `temporarySignedRoute` method.

To create a signedRoute

```
use Illuminate\Support\Facades\URL;
return URL::signedRoute('unsubscribe', ['user' => 1]);
```

To create a temporary signature

```
use Illuminate\Support\Facades\URL;
return URL::temporarySignedRoute(
    'unsubscribe', now()->addMinutes(30), ['user' => 1]);
```

You will also need to validate incoming URL requests with their signatures. You can do this with the `hasValidSignature`. You can also create and define a middleware for this function. The middleware used for this is `Illuminate\Routing\Middleware\ValidateSignature`. Once you have created the middleware, attach it to a route. In case the incoming request is not validated, it will return the 401 error (a necessary evil).

Validation

As your application or website interacts with the user, there will be a fair amount of traffic between the user's browser and system and your server. For obvious security purposes, you need to validate the incoming data. Laravel offers several ways to do this- the default method is using the controller class with a `ValidatesRequests`. It provides a convenient method to validate incoming HTTP request with a variety of powerful validation rules.

Let's assume that you have the routes and controllers created for a form query on your page and you wish to validate the form as it is filled out by the user. The validation code will define a set of rules that are followed sequentially. If the form passes validation, the code will keep executing, if not it will show an error message to the user. The validation rules are to be defined using the `validate` method.

The validation rules can execute completely before the error is shown or it can stop at the first failure. To stop at the first failure, use the `bail` method. You just have to add the `bail` rule to the attribute

```
$request->validate([
    'title' => 'bail|required|unique:posts|max:255',
    'body' => 'required',
]);
```
