

The second argument gives you the option of sending a customized text, this can be ignored at your discretion. If you want to implement this change globally, you can create a `resources/views/errors/404.blade.php`.

Logging

As you develop your application, you need to be able to keep a check on what's happening in the various different pages and logic codes. This is where a log comes into the picture. With a log you can attach messages to files for your reference, see the errors generated and also notify or be notified about the changes being done or implemented by your team. Laravel uses the Monolog library that provides support for a variety of powerful log handlers thereby giving Laravel a robust logging functionality.

The `config/logging.php` configuration file contains all the settings related to logging. You should take your sweet time with this file and understand all the channels and options. By default, Laravel will use the stack channel when logging messages. The stack channel is used to aggregate multiple log channels into a single channel via the `channels` rule.

Also remember, the `level` functionality has to be defined for the error to be successfully logged. Monolog offers the following log levels- alert, critical, error, warning, notice, info, and debug in descending order of urgency. Let's look at a simple log code

```
Log::debug('An informational message.');
```

You can define the level for every channel above which a log will also be sent to that channel. E.g. if you have defined syslog at level critical, any log made in slack which is above critical, will also be logged in syslog by default. By default, the message will be written to the default log channel as configured by your `config/logging.php` configuration file. If you want to write to a specific channel, you will need to specify the channel name using the `channel` method.

```
Log::channel('slack')->info('Something happened!');
```

Remember, these are just beginner tips for you to get started. You should refer to the full documentation on the Laravel website to take a deep dive into it. **d**
