

Components and slots

The models of components and slots are even easier to understand than sections and layouts. Their functionalities and benefits are also similar. Take the following example in which we wish to add a reusable ‘alert’ component for reuse throughout the application:

```
<!-- /resources/views/alert.blade.php -->
<div class="alert alert-danger">
    {{ $slot }}
</div>
```

Example of a Blade layout in Laravel

The ‘\$slot’ variable is used to add content into the component. The ‘@component’ directive is used to create a component:

```
@component('alert')
    <strong>Whoops!</strong> Something went wrong!
@endcomponent
```

After creating the component, we can inject the named slot using the ‘@slot’ directive as follows:

```
@component('alert')
    @slot('title')
        Forbidden
    @endslot
```

You are not allowed to access this resource!

```
@endcomponent
```
