

CSS

The 'package.json' file includes the bootstrap package that can be used to customise the packages that are needed for your application. Laravel gives complete user freedom so you are not required to use the bootstrap framework, but it is better to do so, at least for beginners as it provides a great starting point. The CSS dependencies can be installed using the Node Package Manager (NPM). Once this is done, the CSS files can be compiled using the Laravel Mix framework. The compiled CSS files are stored in the 'public/css' directive.

JavaScript

The JavaScript dependencies are found in the 'package.json' file in the project root directory. Same as CSS, the dependencies can be installed using NPM. once this is done, the 'npm run dev' command can be used to compile the assets. This is again done in the Laravel Mix framework and all the files are stored in the 'webpack.mix.js' file. In case you prefer your own framework, you can do that as well and run your own configuration for the JavaScript application. The compiled JavaScript is typically stored in the 'public/js' directory.

Vue components

If you want to use the default procedure for Laravel for writing JavaScript applications, you use Vue components. Laravel applications have a default

The basic functionality of some applications is to provide proper translation for text strings
