

'example' Vue component stored in them in 'resources/assets/js/components' (which can be deleted if you wish). This file is an example of a single Vue component which defines JavaScript and HTML template in the same file. The component is registered in the 'app.js'

```
Vue.component(
  'example-component',
  require('./components/ExampleComponent.vue')
);
```

If you want to use the component in the application you created, you can drop it into the HTML template. The following is an example of how this can be done:

```
@extends('layouts.app')

@section('content')
  <example-component></example-component>
@endsection
```

You must remember to run the 'npm run dev' command every time you change the Vue component because that command unpacks the package that you want to use. Vue framework can get a little tricky but once you get a hang of it, you will find out that it is seamlessly paired with the Laravel framework.

Conclusion

Laravel is a solid back-end option for any kind of application. It provides a degree of freedom which allows the developer to focus on the stuff that actually matters. Its ease of use and simplicity have been commended worldwide. However, a back-end is not the only aspect of a solid application. A good application is a marriage between an elegant front-end and a solid back-end. Laravel tries its best to make the best out of the situation by providing the developer to choose any framework they seem fit and making Laravel compatible with it. The way Laravel is designed, it is compatible with any java, css or php based framework, and that is what gives it the edge over a lot of other frameworks.
