

Path

We need to setup a path that the user will follow after being successfully registered and authenticated e.g. after successful authentication, user should be redirected to /home url. The location of the redirection can be set using the 'redirectTo' property on any controller. This can also be done by defining the redirectTo logic as shown:

```
protected function redirectTo()
{
    return '/path';
}
```

Username

The default field for authentication in Laravel is the 'email' field. This can however be changed by creating new logic, such as:

```
public function username()
{
    return 'username';
}
```

The guard that is used to authenticate and register the users can also be customized as follows;

```
use Illuminate\Support\Facades\Auth;
protected function guard()
{
    return Auth::guard('guard-name');
}
```

Validation

In order to specify the mandatory fields which need to be filled up for the registry of a new user and to specify a method for the same, we need to add the logic in the 'RegisterController' class. This is the class that is responsible for handling the addition of new authenticated users. The 'validator' method contains the rules for the validation of the new user. This method is completely customizable to the application's functionality. In order to add the records to the master database of users, the 'create' method is used. Once a user is authenticated, you may access the authenticated user via an Illuminate\[Http\Request](#) instance:

```
<?php
namespace App\Http\Controllers;
```
