

```

    * The policy mappings for the application.
    * @var array
    */
    protected $policies = [
        Post::class => PostPolicy::class,
    ];
    /**
     * Register any application authentication / Author-
    isation services.
     * @return void
     */
    public function boot()
    {
        $this->registerPolicies();
        // }}

```

After the registration process is done, various methods such as 'update' may be added. What this method ideally does is decide if a given user has the authorisation to update given information. Instances of this argument would return either a true or false output which can be verified on the basis of the 'user_id'. Other methods like 'add', 'view', 'delete' etc. may be similarly added.

```

<?php
namespace App\Policies;
use App\User;
use App\Post;
class PostPolicy
{
    /**
     * Determine if the given post can be updated by the
    user.
     *
     * @param \App\User $user
     * @param \App\Post $post
     * @return bool
     */
    public function update(User $user, Post $post)
    {
        return $user->id === $post->user_id;    }}

```
