

Argon2 is one of the algorithms that Laravel uses for hashing. It was the winner of the Password Hashing Competition in July 2015

```
if (Hash::needsRehash($hashed)) {  
    $hashed = Hash::make('plain-text');  
}
```

## Conclusion

We have seen the various ways in which we can implement standard security protocol in our web applications. Using other scripting languages would mean creating a tonne of databases and lot more code. This feature is yet another example of how Laravel simplifies all the boring parts of writing the script so you can focus on the stuff that matters i.e. implementing suitable logic in your application. Laravel is truly a framework created by developers, for developers as the community understands the functions that are needed and used the most while developing applications and writing code.
