

Most websites require user to create a password for security purpose. Typing in the following command will enable the user to type in a password on this form.

```
echo Form::password('password');
```

Now that the user has typed in most of his details, he might have to send across a file. Classic examples of this, we all have been asked by job portals to upload our curriculum vitae, haven't we? Typing in this command will enable your form to have that functionality.

```
echo Form::file('image');
```

We all have come across multiple choices in life, especially online, haven't we? Ever had to choose from different age brackets or income slabs while filling an insurance policy form online? The following piece of code gives your form the ability to do so

```
echo Form::checkbox('name', 'value');
echo Form::radio('name', 'value');
echo Form::checkbox('name', 'value', true);
echo Form::radio('name', 'value', true);
```

This is another option to provide the user with multiple options. As the name suggests, the user will be able to click on this to see the list of available options and can then select the appropriate one.

```
echo Form::select('size', array('L' => 'Large', 'S' =>
'Small'));
```

Finally, after filling in all the above details, you'd need to submit the details for validation purposes.

```
echo Form::submit('Click Me!');
```

Form Validation

The next step would be to submit and validate entries to be able to move forward to the next page. Ideally, users will fill the web form with necessary information and finish their job successfully. However, people often make mistakes. This is where web form validation comes into play. The goal of web form validation is to ensure that the user provided necessary and properly formatted information needed to successfully complete an operation.
