

User's input can be validated on the server and on the client (web browser). Thus, we have server-side and client-side validation.

Server-Side Validation

To explain the first half of this literal two-way street, we should understand that this is a secure method. The fact that it cannot be bypassed by malicious users even if JavaScript is turned off, is consolation enough that it can be securely used. Once the information is sent to the server, it is validated using one of the server-side languages. What happens if the validation fails? It is simply sent back to the client page along with a feedback or explaining the validation failure. On the flipside, it could get a tiny bit tedious as success or failure of validation is only known after having filled out the information wholly. This results in a slow response from the server.

Client-Side Validation

Client-side validation is known to have a better experience for users as opposed to server-side application which gives you the bare minimum successful and secure validation of your form. Client-side validation is done using JavaScript. This validation is done on the client-side languages of which JavaScript is an example. As opposed to server-side validation, this one is more of a realtime validation and there is no need to await the completion and submission of the form. It validates user's input as it being typed in.

Uploading files via forms

Online form submissions are almost an essential feature on large networking platforms. A few good examples of these could be anything from your college application, medical record, feedback forms, scanned document submissions, datasets populated on excel sheets, copies of your resume or curriculum vitae while looking for job. If you need to develop a website with a feature to upload forms, Laravel has a solution for this too. It supports the upload of files with different extensions. These could be text documents like .doc, excel sheets like .xls. Images or scans with extensions like .pdf, .jpeg and .png. Uploading Files in Laravel is easy. All we need to do is to create a view file where a user can select a file to be uploaded and a controller where uploaded files will be processed.

In a view file, we need to generate a file input by adding the following line of code.

```
Form::file('file_name');
```
