

The web's most popular framework

Today's web developer is by no means short of programming languages to build the next big web platform. The same can be said for frameworks, of which one can find quite a lot with a myriad set of features spread between them. However, there's also a problem that plagues the current web-dev scene and it has to do with the insane number of elements that come together for any project. There's a framework for the front-end, umpteen number of middle-ware and an equally exhaustive set of components for the back-end. Rarely is there a one-for-all kind of solution. We aren't saying that Laravel is that panacea for all your web-dev problems but it certainly does come close.

As of writing this, Laravel has 41,367 stars on Github which is a testament to the popularity of this framework that was created barely 7 years back. It's heavily used in the industry thanks to its support for Model-View-Controller conventions and syntactic sugar i.e. making it easier for the developer to read and write the language. The simplicity of Laravel allows for developers to rapidly bring ideas to life. Because of its ballooning popularity and the fact that it is open-source, a vast community has developed around the framework leading to the birth of many packages that extend Laravel's functionality.

We chose Laravel because of the fact that it offers better performance, more features and better scalability with respect to all the web frameworks out there. Laravel was born out of the desire to compensate for the shortcomings of another PHP framework which was equally popular in its heyday. There are many others in its league, such as CodeIgniter, YII, Zend, CakePHP, Falcon, etc. While some may argue that CodeIgniter is simpler as a framework, or that Falcon is way faster, there is no arguing
