

Need to send across emails from your web platform? Laravel does it brilliantly.

The code to use for building you message:

```
/**
 * Build the message.
 * @return $this
 */
public function build()
{
    return $this->view('emails.orders.shipped');
```

Configuration

A configuration file is a storehouse of data that is needed for a specific use. Laravel has a config directory where all the configuration files are saved. There are several choices to pick from and all of them categorized rather brilliantly helps you browse, pick and choose what you need. Accessing a configuration file is easy and can also be done at run-time. However, when you do them at run-time, they cannot be carried over to other requests and can only be done on current ones. How would you do this? Simply use `Config::get`. What happens in the event a configuration value that you are looking for does not exist? Laravel allows to specify default values. For example, if you are trying `Config::get('app.timezone')`; and it does not exist. You simply use a default value like `$timezone = Config::get('app.timezone', 'UTC');`
