

We've all worked in teams and understand the value of clear communication and the perils of duplication. How many times have you sat at your work desk and thought thank god for shared drives. You can carry with using an .env file with your application. This can be achieved by putting placeholder values in the example configuration file. When you do this, your teammates will be able to see quite clearly the environment tables that are needed to run your application. If you create an .env.testing file, it will override the .env file when running PHPUnit tests. It will also do this when you are executing Artisan commands with the --env=testing option.

What is custom domain?

We've all heard the term 'custom domain' at some point or the other and few might actually know what is used for and its benefits. Simply put, it is your unique business name getting a space in the virtual world. As a business, you ought to have a unique presence on the web for your brand to sell well. Businesses that establish this step usually perform way better than the ones who haven't registered a custom domain for their business yet.

Active bloggers would be quite familiar with this term, as you get a domain like 'yourblog.blogspot.com' Professional bloggers have known for a fact that such domains are bad for business.

You've invested several months creating a brand; don't ruin the efforts by not using a custom domain!
