

Database

Where there is a framework, there often is a database. Here's how Laravel plays with the most popular databases.

Databases are part and parcel of learning every programming language. You will have to learn the steps involved in establishing connectivity with databases after mastering the fundamentals.

If you look at the Microsoft languages such as C# or Visual Basic, you will work with Microsoft SQL Server. If you work with PHP, you will have to learn concepts involved with MySQL or PostgreSQL. The database connectivity process for Microsoft-centric languages have been simplified with the emergence of Visual Studio. You can directly connect the program with the relevant database without any coding. However, for advanced tasks you will have to switch to the code editor to enable the software or web application to perform complex tasks. If you work with Laravel, you will have to provide all the code and execute them on the command terminal
