

can create an Eloquent model. even though models are housed in the app directory, you can include them at any location. However, they will automatically load as per the configuration provided on the `composer.json` file. It is to be noted that all Eloquent models extend `Illuminate\Database\Eloquent\Model` class. You can easily create a new instance of the model with the help of the `make:model` Artisan command as shown below:

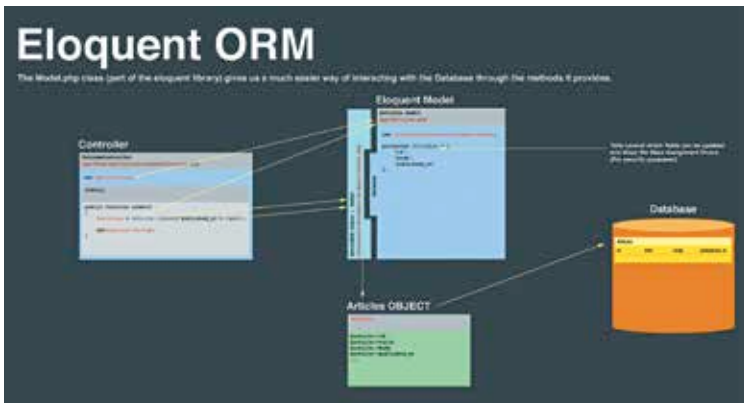

```
php artisan make:model User1
```

you can also use the `--migration` or `-m` options if you would like to kick start a database migration process during the model generation:

```
php artisan make:model User --migration
```

```
php artisan make:model User -m
```

If you work with Eloquent using Laravel, you should create a primary key column. However, you can define a `$primaryKey` property, which will be protected to override the standard convention. The primary key will be assigned to an `int` variable since the Eloquent ORM assumes that the defined primary key is an integer value that increments automatically. You can make use of a primary key that doesn't increment but you should apply `$incrementing` property to false on your model.

Working with Eloquent ORM using Laravel

The `$keyType` property should be modified to string if the variable assigned to the primary key is not an integer. Moreover, you need to configure `created_at` and `updated_at` columns while designing the tables. It is possible for the ORM to skip these columns by setting `$timestamps` property on your model to false. The timestamps format can be customized
