

Lara-who?

Laravel. What's that, you ask? Simply put, Laravel is an open source web framework that helps in the development of web-based applications that are used rather widely today. What started out in the middle of 2011 at its first ever released version, today has a wide global presence and numerous improvisations now to have reached a level of robustness, reliability and perfection.

Where Can Laravel Ideally Be Used?

Laravel is supported by the Model View Controller (MVC) architecture. Laravel brings to the table a good variety of inbuilt features for the user to choose from. You can be someone who is looking to design a local app with basic features or you could be developing something that could take humankind by storm. Laravel gives all its users the option to install third party packages which will save developers much time while creating their application. A classic example of this would be insert a commonly used function. Surely this function will easily be available with a third party. Laravel assisting and encouraging you to use these packages makes your life a tad bit simpler, doesn't it? Also, as an added bonus, these installed packages can also be upgraded if needed.

Think about it. Surfing the web for most people comes naturally to us these days. This is because we are used to certain patterns commonly seen on most websites. These include forms, user authentications, help sections, simple message templates, etc. As mentioned here, these are pretty generic for most websites. Laravel has made life even easier for you. By definition, a library is an assemblage of the aforementioned resources. Laravel makes available to you, at least twenty such libraries and they come already installed for you to pick and choose from.

All of this makes Laravel the ideal choice when it comes to creating web applications that could range from an simple app or a full fledged one.

Laravel And The Competition:

While there are more than a few other PHP frameworks which have been around for as long or longer than Laravel, this seems to be the obvious choice for most. A quick check on Google Trends will tell you that Laravel is the better framework out there or at least the more preferred one when compared to its counterparts like CodeIgniter, CakePHP or Zend. Here are a few reasons why Laravel is outdoing the others
