

Lastly is the Layers option that opens up the list of all the objects that you have used. Double-clicking on the layer name enables changing its name. Hovering the mouse pointer on the name also makes some more options available. From left to right, Mark for Batch Export lets you create a special list of layers that you want to export exclusively, enabling Lock removes the ability to interact with the respective layer and Hide toggles the layer between being visible and invisible.

Property Inspector

Upon using a tool, the section on the right edge lights up. This is a dynamic section that changes based on the tool you're using.

When the Select tool is used to select an object, the inspector shows a variety of options to edit the object. Clicking on the title of an artboard while using the Select tool, selects the whole artboard and the inspector changes to provide options for that.

Starting from the top left are the eight alignment options. When only one object is selected, the object is aligned according to the artboard. When two or more objects are selected, the alignment happens in relation to each of the objects. Align Top, Align Middle (Vertical), Align Bottom, Align Left, Align Middle (Horizontal) and Align Right align the objects as they're titled. When three or more objects are selected, two remaining options become available to use. Distribute Horizontal and Distribute Vertical equalize the spacing between the selected objects.

Moving down a notch, Repeat Grid turns the selected object, or a group of objects, into a repeatable pattern. Two handles appear around the selection which when pulled expand the pattern. The spacing between each cell of the pattern can be simultaneously adjusted using the pink highlighted space, that appears when the mouse is brought over the space between the cells. To make changes to the cells, any one of them can be double clicked on to edit the shape. All the changes on the cell are live and are instantly reflected on others.

Next up are the four Boolean operations - Add hides all the intersecting path segments amongst the shapes. Subtract hides everything except the area that isn't overlapped by any shape, it won't have an effect if there are no areas being overlapped. Intersect hides everything except the area overlapped by the most shapes, it won't have an effect if there is no shape being overlapped. Exclude Overlap toggles the visibility of the area whenever it gets overlapped.
